

### **ABSTRACT OF THE DISCLOSURE**

A motor vehicle with an automobile body having two rigid body regions located on both sides above side window regions. At least two panel-shaped roof sections lay behind one another between the two body regions, which roof sections can move relative to the lateral body sections, and can move out of the closed position into an open position further below in the automobile body. From the closed position of the roof sections, a front roof section can be moved over a rear roof section by guiding it laterally like a sliding sunroof. The front end regions of the roof sections can be raised from this position so that the roof sections can be lowered into the automobile body. In the closed position of the roof sections, a rear window, which can be separately moved between an open position and a closed position, borders directly on the rear roof section.
